Abstract

5 In a process for preparing ω -hydroxyesters of α,β -unsaturated carboxylic acids, a vinyloxy ester of the carboxylic acid is treated with a strong acid in the presence of an alcohol, in particular a 1,2-diol or 1,3-diol.

Preparation of ω -hydroxyesters of α,β -unsaturated carboxylic acids

- 5 The present invention relates to a process for preparing ω -hydroxyesters of α,β -unsaturated carboxylic acids.

Hydroxy-functional esters of α,β -unsaturated carboxylic acids, in particular hydroxy-functional (meth)acrylates, are important
10 comonomers for polymers which are used, for example, in paint dispersions, as coating resins or for preparing polyurethane

- DE-B-1 255 104 discloses preparing β -hydroxyalkyl esters of acrylic and methacrylic acid from the corresponding acid and 1,2-alkylene oxides (eg. ethylene oxide or propylene oxide). The process has the disadvantage that gaseous ethylene oxide or propylene oxide must be handled. In addition, longer-chain
20 ω -hydroxyalkyl esters of α,β -unsaturated carboxylic acids cannot be prepared in a similar manner.

- DE-B-1 518 572 and EP-A-465 853 describe processes for preparing ω -hydroxyesters by acid-catalyzed esterification of diols with
25 acrylic or methacrylic acid. However, as a disadvantage in these esterification processes, cyclic ethers are formed as byproducts. As is disclosed, for example, by Houben-Weyl, Methoden der Organischen Chemie, [Methods in organic chemistry] VI/3, 1965, p. 528, 1,4-butanediol, in the presence of strong acids, produces
30 the cyclic ether tetrahydrofuran, which has very low biodegradability and is thus an environmental pollutant.

- Since the diols have two equivalent hydroxyls, in the esterification, even in the event of a great diol excess,
35 considerable amounts of the corresponding diesters are always formed, as is disclosed by EP-A-465 853, p. 3, lines 25-34. Fractionation of the esterification mixture by distillation is not generally possible, because of the small boiling point
40 differences and the high boiling points, since the esters of α,β -unsaturated carboxylic acids, and in particular the esters of acrylic and methacrylic acid, are known to polymerize very readily at elevated temperatures.

- 45 Fractionating esterification mixture using column chromatography, as is disclosed, for example, by Makromol. Chem. Rapid Commun., 9 (1988), (7), pp. 503-511, and enzymatic hydrolysis of the

2

diesters to give the corresponding monoesters of the diols, disclosed by JP-A-63 237 791, are not industrially and economically expedient, because of the low space-time yields and the high solvent requirement.

5

Diol, monoester and diester can be separated, as disclosed by EP-A 465 853, by extracting diester with an organic solvent and washing the extract with water to separate off the co-extracted monoester. Since high water solubility of the monoester is a prerequisite, this process is restricted to preparing esters of (meth)acrylic acid with short-chain diols.

10

EP-A-465 853 also discloses preparing 4-hydroxybutyl (meth)acrylate in the presence of large amounts of 1,4-butanediol di(meth)acrylate, in order to increase the yield of monoester. It is a disadvantage in this process that the large amounts of diester also have to be completely removed again and recycled to the esterification, i.e. that large amounts of diester have to be recirculated. No details are given on the diester content in the monoester.

15

20

DE-A-4 228 397 describes a process for preparing hydroxyalkyl (meth)acrylates by reacting the corresponding hydroxyalkyl halides with (meth)acrylic salts. Owing to the use of halogen compounds and salt formation, this process is not harmless from the ecological viewpoint. In addition, diester-free monoester is not formed - up to 2% of diester is formed (p. 3, line 24).

25

US-A-2 877 264 describes a process for preparing hydroxyalkyl acrylates and methacrylates by acid hydrolysis of the corresponding vinyloxyalkyl (meth)acrylates (vinylether cleavage). However, the yield leaves something to be desired; in the case of 1,4-butanediol it is only 35-51%. Further disadvantages are the high water requirement of the process and the necessity of using an additional solvent. Both complicate the work-up and pollute the environment.

30

35

US-A-2 692 256 discloses preparing vinyloxyalkyl esters of unsaturated carboxylic acids by transesterification from the corresponding vinyloxy alcohols and esters of α,β -unsaturated carboxylic acids with lower alcohols in the presence of alkaline metal alkoxides or quaternary ammonium alkoxides. Disadvantages here are the laborious work-up and the unsatisfactory yields.

40

45

3

It is an object of the present invention to provide an environmentally acceptable and generally applicable process for preparing ω -hydroxyesters of α,β -unsaturated carboxylic acids in high yield and purity, in which no undesirable byproducts such as cyclic ethers or diesters are produced.

We have found that this object is achieved by a process for preparing ω -hydroxyesters of α,β -unsaturated carboxylic acids, in which

- 10 a) an ester of the α,β -unsaturated carboxylic acid is transesterified by a vinyloxy-containing alcohol in the presence of basic catalysts to give the corresponding vinyloxy carboxylic ester and b) the vinyloxy carboxylic ester is reacted in the presence of strong acids as catalyst to give the corresponding
- 15 ω -hydroxyester, which comprises carrying out step b) in the presence of an alcohol, preferably a 1,2-diol or a 1,3-diol.

The course of the reaction is illustrated by reaction scheme 1.

- 20 The 1,2-diol used here as an example is ethylene glycol.

Reaction scheme 1

where

- 45 R^1 is H, or $\text{C}_1\text{-C}_4$ -alkyl,
- R^2 is H or CH_3 ,

- 4
A is C₂-C₁₂-alkylene, preferably C₂-C₆-alkylene,

or $\text{---}(\text{CH}_2)_o\text{---B---}(\text{CH}_2)_p\text{---};$

- 10 Q is C₁-C₆-alkyl, preferably CH₃ or C₂H₅,
 R¹ H or CH₃,
 B is an arylene, preferably phenylene, cycloalkylene, preferably cyclopentylene or cyclohexylene, or an oxygen;
 15 n is a number in the range from 1 to 10;
 o and p independently of one another are a number in the range from 1 to 5.

- 20 The alkyls are unbranched or branched radicals such as methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, sec-butyl, tert-butyl, n-pentyl, isopentyl, n-hexyl and isohexyl.
 C₂-C₁₂-alkylene is unbranched or branched C₂-C₁₂-alkylene, such as
 25 ethylene, n-propylene, n-butylene, 2-methylpropylene, n-pentylene, 2,2-dimethylpropylene, n-hexylene, n-heptylene, 3,3-dimethylpentylene, n-octylene, n-nonylene, n-decylene, n-undecylene and n-dodecylene.

- 30 Alcohols which can be used for the transesterification reaction in step a) are, in particular, 1,4-dimethylolcyclohexane monovinyl ether, 1,4-dimethylolbenzene monovinyl ether, 5-vinyloxy-pentanol, 6-vinyloxyhexanol and, particularly preferably, 4-vinyloxybutanol. Preferably, alcohol and ester
 35 components are used in a molar ratio of from about 1:1.5 to 1:10, particularly preferably from about 1:2 to 1:6.

- Basic transesterification catalysts are known to those skilled in the art. Suitable examples are alkaline metal alkoxides, such as
 40 potassium t-butoxide, sodium methoxide, sodium ethoxide and potassium propoxide, as well as quaternary ammonium alkoxides, such as tetramethylammonium methoxide, tetramethyl ammonium tert-butoxide, trimethylbenzylammonium ethoxide and, in particular, zirconium acetylacetonates, dialkyltin oxides,
 45 lithium salts or calcium salts, such as LiCl, LiNO₃, Ca(RO₃)₂, CaCl₂, or lithium oxide or hydroxide, or calcium oxide or hydroxide, or mixtures of these, and, particularly preferably,

CA 01221543 1997-11-11

M/37102

titanium alkoxides. The catalysts are expediently used in an amount of from 0.05 to 10% by weight, in particular from 0.1 to 5% by weight, in each case based on the reaction mixture.

- 5 The polymerization inhibitors used are, eg. phenothiazine, hydroquinone, hydroquinone monomethyl ether, or mixtures of these with or without air (from 0.1 to 10 l/hour x l) in an amount of from 100 to 5000 ppm, based on the reaction mixture.
- 10 The transesterification reaction temperature is generally from about 50 to 150°C, preferably from about 70 to 130°C.

The reaction time can be varied in a broad range. It is generally 15 from about 1 to 10, preferably from about 1 to 6 hours.

The reaction can be carried out under atmospheric, superatmospheric or reduced pressure. It can be carried out continuously or batchwise.

20

The reaction is carried out in conventional apparatuses, eg. in a heatable stirred reactor, which may be equipped with a distillation apparatus and condenser. The reactor contents are mixed by stirring or by other conventional and appropriate

25 measures.

The alcohol Q-OH formed in the transesterification is preferably continuously distilled off from the reaction mixture, if 30 appropriate as an azeotrope, together with the starting ester.

The vinyloxy carboxylic ester formed by the transesterification can be obtained from the reaction mixture without prior removal of catalyst or neutralization in a conventional manner, eg. by 35 distillation in a sieve-tray column.

In step b), in principle any alcohol can be used, but preferably 1,2-diols and 1,3-diols, but preferably those diols whose acetal boils below the reaction product. Generally, an alkanediol is 40 used, in particular a C₂-C₆-diol. However, preference is given to 1,2-propylene glycol and particular preference is given to ethylene glycol. The 1,2-diol is generally used in an at least equimolar amount, preferably up to 30% molar excess, in particular up to 10% molar excess, based on the vinyloxy 45 carboxylic ester.

6

The vinyl ether cleavage is carried out in the presence of catalytic amounts (from about 500 to 5000 ppm, based on the amount of diol used) of a strong acid. Useful strong acids are, for example, phosphoric acid, hydrogen chloride or, preferably, methanesulfonic acid or p-toluenesulfonic acid or, particularly preferably, sulfuric acid or acid ion exchangers.

The vinyl ether cleavage proceeds exothermically generally at from about 5 to 50°C, in particular at from about 20 to 40°C. It is kept within said range by cooling and/or controlling the feed rate of the vinyloxyalkyl carboxylate. The reaction time is generally from about 1 to 10 hours, in particular from about 1 to 5 hours.

The reaction is carried out in a conventional coolable and heatable reaction vessel, preferably a stirred reactor, which may be equipped with a distillation apparatus and condenser.

The reaction may be carried out continuously or batchwise. It is preferably carried out under reduced pressure (from 1 to 100 mbar).

Diol and acid are expediently charged into the reaction apparatus and the vinyloxy ester is slowly added under reaction conditions.

Alcoholysis of the vinyl ether with 1,2-diols gives the corresponding cyclic acetals, as are disclosed by, inter alia, Houben-Weyl, Methoden der Org. Chemie [Methods in organic chemistry], VI/3, 1965, pp.329-330, which may be readily isolated by distillation. The distillation may be performed under reduced pressure or by stripping with air.

After completion of the reaction, the catalyst can be neutralized with a base, eg. alkali metal oxide or hydroxide, bicarbonate or carbonate, or alkaline earth metal oxide or hydroxide, bicarbonate or carbonate, with or without a little water, and separated off. Any excess diol still present is advantageously extracted, jointly at the same time. The end product is generally produced in adequate purity, and does not require further purification. The yield is at least 95%. An additional purification by distillation under reduced pressure may proceed in a conventional manner.

The acetal formed in the reaction is continuously distilled off.

The examples below illustrate the invention, but without restricting it to these. Percentages are mola.

Example 1 (Transesterification)

In a stirred reactor having an attached distillation column, a mixture of 348 g of 4-vinylxybutanol, 1003 g of methyl methacrylate, 10.5 g of titanium tetrabutoxide, 1 g of phenothiazine and 0.5 g of hydroquinone monomethyl ether is heated to boiling, 10 l of air being continuously introduced into the reaction mixture. The methanol formed in the reaction is continuously ejected at the top of the column as an azeotrope with methyl methacrylate. After a reaction time of 5 hours, the reaction mixture is worked up by distillation under reduced pressure, the recovered excess methyl methacrylate being reused. 501 g of 4-vinylxybutyl methacrylate (b.p. 82-83°C/4 mbar) are obtained. The yield is 91%.

20 Example 2 (vinyl ether cleavage)

112 g of ethylene glycol and 80 mg of sulfuric acid are introduced into a coolable stirred reactor equipped with a distillation apparatus and 333 g of 4-vinyl-oxybutyl methacrylate (stabilized with 350 ppm of hydroquinone monomethyl ether) are added, the pressure in the reactor being 10 mbar. The addition is controlled in such a manner that the reaction mixture does not exceed 35°C. The acetal formed in the reaction is continuously distilled off (b.p. 82°C). After a reaction time of 3 hours, the mixture is neutralized with 0.5 g of magnesium oxide and filtered. 281 g of 4-hydroxybutyl methacrylate having a purity determined by gas chromatography of 97% (yield: 98%) are obtained. The diethacrylate content is less than 0.1%.

We claim:

1. A process for preparing ω -hydroxyesters of α,β -unsaturated carboxylic acids, in which
 - a) an ester of the α,β -unsaturated carboxylic acid is transesterified by a vinyloxy-containing alcohol in the presence of basic catalysts to give the corresponding vinyloxy carboxylic ester, and
 - b) the vinyloxy carboxylic ester is reacted in the presence of strong acids as catalyst to give the corresponding ω -hydroxyester,
 which comprises carrying out step b) in the presence of an alcohol.
2. A process as claimed in claim 1, wherein the alcohol used is a 1,2-diol or a 1,3-diol.
3. A process as claimed in claim 1 or 2, wherein the ester of an α,β -unsaturated carboxylic acid used in step a) corresponds to the formula I

the vinyloxy-containing alcohol used in step a) corresponds to the formula II

the vinyloxy carboxylic ester prepared in step a) corresponds to the formula III

and the ω -hydroxy ester prepared in step b) corresponds to the formula IV

where

R¹ is H or C₁-C₆-alkyl,

R² is H or CH₃,

A is a C₂-C₁₂-alkylene,

or $\text{---}(\text{CH}_2)_o\text{---B---}(\text{CH}_2)_p\text{---}$,

Q is C₁-C₆-alkyl, preferably CH₃ or C₂H₅,

R³ is H or CH₃,

B is an arylene, in particular phenylene, cycloalkylene, in particular cyclopentylene or cyclohexylene or an oxygen,

n is a number in the range from 1 to 10, and

o and p independently of one another are a number in the range from 1 to 5.

4. A process as claimed in one of the preceding claims, wherein the ester of the α,β -unsaturated carboxylic acid used in step a) is an ester of acrylic or methacrylic acid with a C₁-C₆-alcohol.

5. A process as claimed in one of the preceding claims, wherein the alcohol used is 5-vinyloxypentanol, 6-vinyloxyhexanol or, in particular, 4-vinyloxybutanol.

6. A process as claimed in one of the preceding claims, wherein the alcohol and ester components are used in the transesterification reaction in a molar ratio of from about 1:1.5 to 1:10, in particular from about 1:2 to 1:6.

7. A process as claimed in one of the preceding claims, wherein, as basic catalysts, use is made of zirconium acetylacetonates, dialkyltin oxides, lithium salts or calcium salts or their oxides or hydroxides, or, in particular, titanium alkoxides.

8. A process as claimed in one of the preceding claims, wherein the basic catalysts are used in an amount of from 0.05 to 10% by weight, in particular from 0.1 to 5% by weight, in each case based on the reaction mixture.

3

9. A process as claimed in one of the preceding claims, wherein the vinylloxycarboxylic ester in step a) is purified by distillation without prior removal of the catalyst or neutralization.

5

10. A process as claimed in one of the preceding claims, wherein the 1,2-diol used is ethylene glycol or 1,2-propylene glycol.

10

11. A process as claimed in one of the preceding claims, wherein the 1,2-diol is used in from about 0 to 30%, in particular from about 0 to 10%, molar excess, based on the vinylloxycarboxylic ester.

15

12. A process as claimed in one of the preceding claims, wherein the strong acid used is phosphoric acid, hydrogen chloride or, in particular, methanesulfonic or p-toluenesulfonic acid, sulfuric acid or acid ion exchangers.

20

13. A process as claimed in one of the preceding claims, wherein, in step b), the reaction is carried out at from about 5 to 50°C, in particular from about 20 to 40°C.

25

14. A process as claimed in one of the preceding claims, wherein step b) is carried out at reduced pressure or with air-stripping.
